

A Gaussian shell of amplitude ε multiplies the conformal factor at $t=0$. Since $R \propto \psi^2$ the arms start 2ε apart: that offset is the kick.

Each throat first moves the way it was pushed, returns, and crosses at $t \simeq 13.1$ (dotted). Only after the crossing does the fate declare itself, with the opposite sign.

Pale: the ray scan's minimum has reached its inner cutoff ($r=0.53$) and no longer tracks the throat — $\varepsilon = +0.01$ from $t=29$. Nothing after that point is a measurement of the throat.

Growth rate still settling ($\varepsilon = -0.01$: 0.12, $\varepsilon = +0.01$: 0.20; level 3's own seed gives 0.17), so none is quoted. Level 3, stop time 100; as of this build, -0.01 to $t=35$, +0.01 to $t=35$.
